Stellar Cyber 6.6.0s is now live! Discover all the updates in the release notes!

Understanding Alert Auto Triage Performance

The Alert Auto Triage feature is only supported on Stellar Cyber in SaaS deployments and requires an add-on license, which you can request from your sales representative. If you used this feature through participation in the Early Access Program, contact your sales representative to continue with an add-on license or to request that the service be disabled.

Understand what happens during the Alert Auto Triage process, why it can take several minutes to complete, and how to interpret the observed latency in production environments.

- **Why Auto Triage Takes Several Minutes**
- **Observed Production Latency**
- **Interpreting Latency in Context**

What Happens During Auto Triage

When the Stellar Cyber Platform processes an alert through Auto Triage, it does not perform a single check. Instead, it launches AI agents that execute a comprehensive sequence of investigative steps—comparable to the work a Tier 1 SOC analyst would perform manually. The investigation includes these steps:

- Enriching observables (IP addresses, domains, file hashes, URLs) against threat intelligence feeds and reputation services such as VirusTotal, AbuseIPDB, and URLscan.
- Querying endpoint telemetry from integrated sources such as SentinelOne Deep Visibility and Microsoft Defender to retrieve process-level context, device compliance status, and event history.
- Performing real-time identity lookups against platforms such as Okta and Entra ID to retrieve user profile metadata, activity history, and VIP status indicators.
- Running Verdict Signal Checks (VSCs) across process, network, file, and identity observables.
- Correlating findings across multiple data sources and detection layers.

- Synthesizing all evidence into a verdict (True Positive, Benign True Positive, False Positive, or Inconclusive) with a structured narrative explaining the reasoning.

Each of these steps involves external API calls, data correlation, and AI reasoning. The depth of this analysis is what enables high-confidence verdicts and reduces the need for manual investigation.

Why Auto Triage Takes Several Minutes

The time required for Auto Triage reflects the depth and breadth of the investigation being performed. This is similar to how modern AI assistants take several minutes when performing complex research tasks. The system is reasoning, gathering information from multiple sources, and synthesizing results rather than returning a cached or precomputed answer.

A Tier 1 analyst typically spends two to four hours per case on a manual investigation of equivalent depth. Alert Auto Triage completes the same work in minutes, and it does so continuously, 24/7, without fatigue or capacity constraints.

Observed Production Latency

The following table shows observed latency percentiles from production environments as of April 2026. These values represent real-world performance across a range of alert complexities and case sizes.

Case Triage Latency

Case triage latency measures the time to complete the case-level summary and narrative after all associated alerts have been triaged. The following table presents case triage latency by percentile.

Percentile	Latency	Description
p50 (median)	~2.4 minutes	Half of all cases are fully triaged in under 2.5 minutes.
p95	~6.4 minutes	95% of cases complete within approximately 6 minutes.
p99	~10.6 minutes	Only 1% of cases exceed approximately 10 minutes.

Case triage latency is generally lower at the high percentiles than alert triage latency because the case-level summary synthesizes the investigation work already completed at the alert level. It performs aggregation and narrative generation rather than repeating the underlying investigation steps.

Interpreting Latency in Context

When evaluating Auto Triage performance, consider the following factors to interpret latency in context:

- **Speed vs. depth** – Latency reflects the thoroughness of the investigation. Faster results would require reducing the number of enrichment sources or validation checks, which would lower verdict confidence.
- **Minutes vs. hours** – The relevant comparison is not against instant classification, but against the 2–4 hours a human analyst would need to perform the same investigation

manually. Auto Triage delivers equivalent depth in a fraction of the time.

- **Continuous operation** – Auto Triage runs 24/7 without breaks, fatigue, or capacity limitations tied to analyst availability. This means that even alerts arriving outside business hours or during peak volume periods receive the same depth of analysis.
- **External dependencies** – A portion of the latency—particularly at the p95 and p99 levels—is attributable to external API response times from threat intelligence and enrichment providers. These are outside the control of the Stellar Cyber Platform but are necessary for high-confidence verdicts.
